

# Electron reconstruction and selection in CMS Higher Level Trigger

Kati Lassila-Perini  
CMS Collaboration  
Helsinki Institute of Physics

## Outline:

- Why electrons?
- Level 1 selection
- Higher Level Trigger selection
- Complete online selection for low luminosity

**Where do we get electrons in 14 TeV pp collisions?**

- Electrons from the primary vertex:

$$Z \rightarrow e^+e^-$$

$$W^\pm \rightarrow e^\pm \nu_e$$

$$\pi^0 \rightarrow (e^+e^-)\gamma \text{ (Dalitz decay)}$$

- Electrons from a displaced vertex:

$$b \rightarrow e^\pm$$

$$b \rightarrow c \rightarrow e^\pm$$

$$\tau^\pm \rightarrow e^\pm \nu_e \nu_\tau$$

$$\gamma \rightarrow e^+e^-$$

**Why do we want to see the electrons?**

- leptonic decays of the Higgs boson and supersymmetric particles
- leptonic tagging of hadronic decay modes
- calibration.

**Main SM Higgs discovery channels**

**Parameter space coverage in MSSM**

**What does an electron look like in CMS?**

**B-field**

**Material**

$r_{calorimeter} = 130 \text{ cm}$   
 $B\text{-field} = 4 \text{ T}$   
 electrons of interest  $p_T \gtrsim 5 \text{ GeV}$

- Tracker:  $0.4 - 1.2 X_0$  of material
- $X_0$ : Bremsstrahlung E loss on the average  $1 - 1/e = 63.2\%$

$p_T$       Deviation      Crystal size  
 at ECAL     $22 \times 22 \text{ mm}$

|        |        |
|--------|--------|
| 10 GeV | 10 cm  |
| 15 GeV | 6.7 cm |
| 25 GeV | 4.0 cm |
| 50 GeV | 2.0 cm |

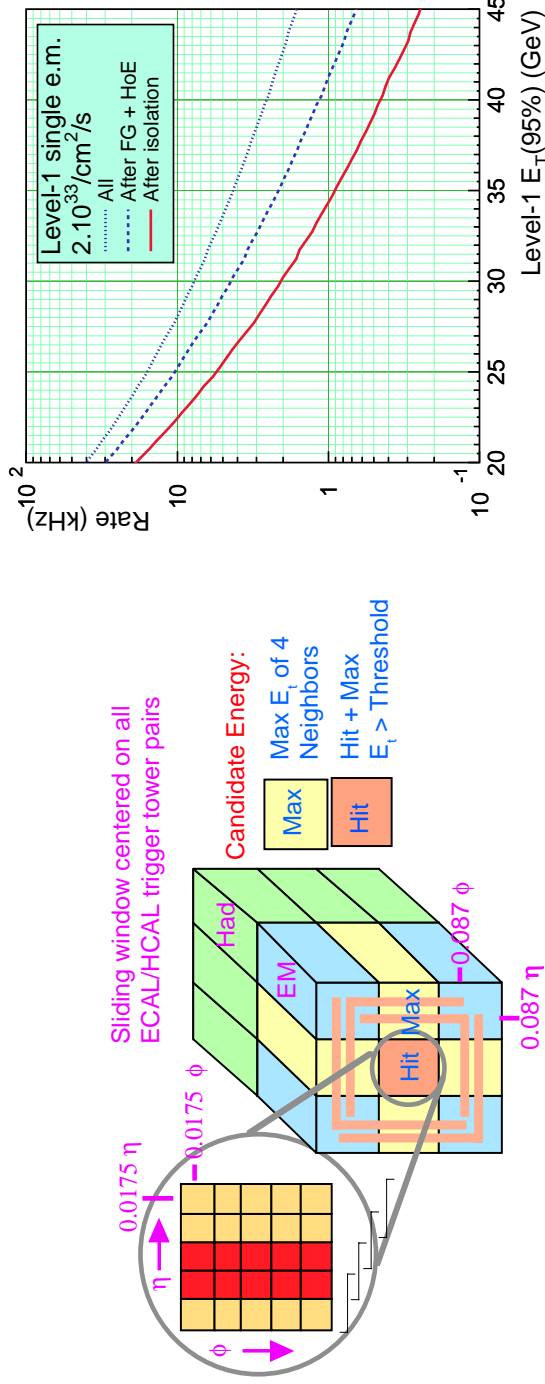

- $\Rightarrow$  we **must** recover the radiated photon E in ECAL
- $\Rightarrow$  we **can** have a dedicated  $e^\pm$  track reconstructor.

## Level 1 triggers

- Low luminosity ( $2 \cdot 10^{33} \text{ cm}^{-2} \text{ s}^{-1}$  first years of the LHC running)
  - maximum **50 kHz**
  - safety factor 3:  $50/3 \approx 16 \text{ kHz}$
  - four trigger groups **4 kHz** each:
    - electromagnetic (single and double electron/photon)
    - $\mu$  (single and double)
    - jets (1, 2, 3 or 4 jets, missing  $E_T$ )
    - mixed ( $\tau + e$ , jet + e,  $e + \mu$ , etc)
- Electromagnetic trigger (only calorimeter, no tracker)

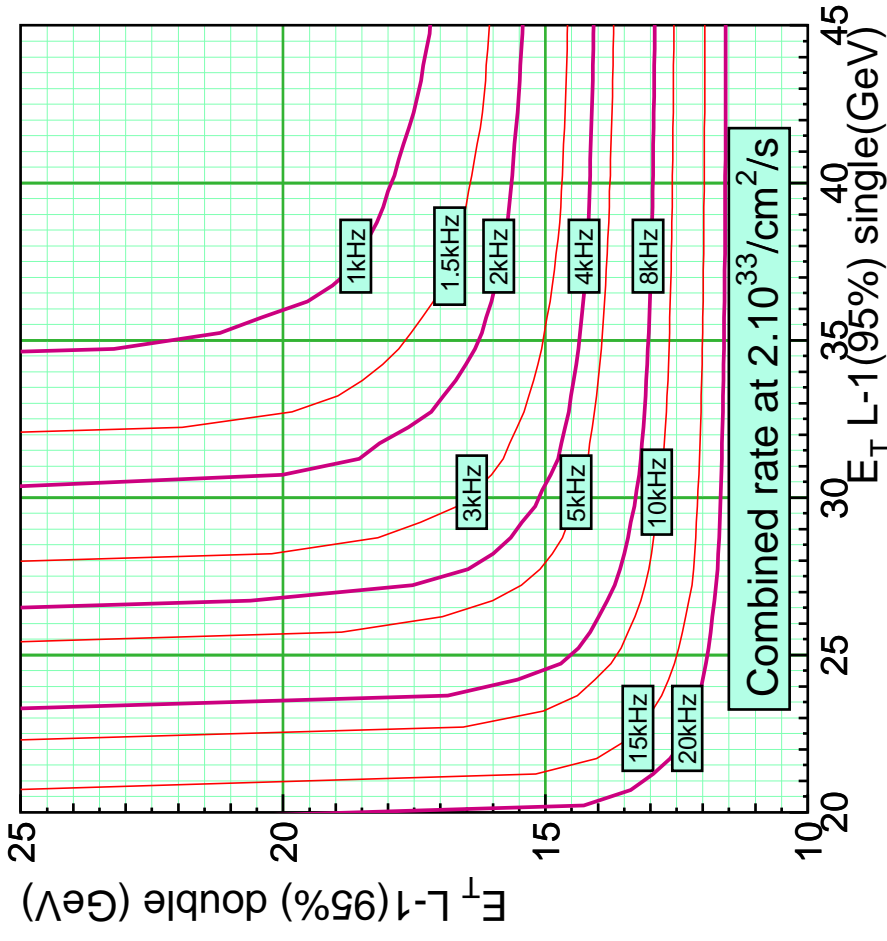

P

At level 1, the rate is completely dominated by fake electrons, e.g. jets with a leading, energetic  $\pi^0$ .

## The Level 1 trigger thresholds

- We have 4 kHz at our disposal for low luminosity
  - how to share this between the **single** e.m. and the **double** e.m. triggers?
- Choose the thresholds by optimizing the efficiency for signal
  - $Z \rightarrow e^+e^-$
  - $W \rightarrow e\nu$ .

## Optimizing the Level 1 trigger thresholds

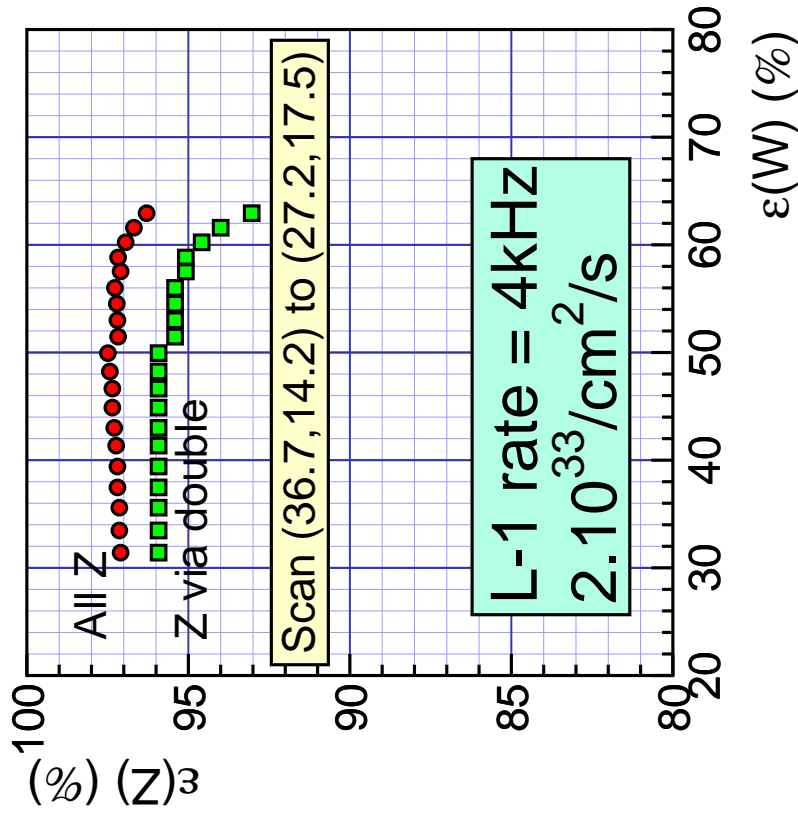

- Take trigger threshold values from the 4 kHz contour
  - scan from (high single, low double) to (low single, high double)

and see what happens to the signal efficiency.

- High efficiency for  $W \rightarrow e\nu$  is reached at low single threshold values.
- The efficiency for  $Z \rightarrow e^+e^-$  remains constant down to fairly low single threshold values.

⇒ Choose the operation point

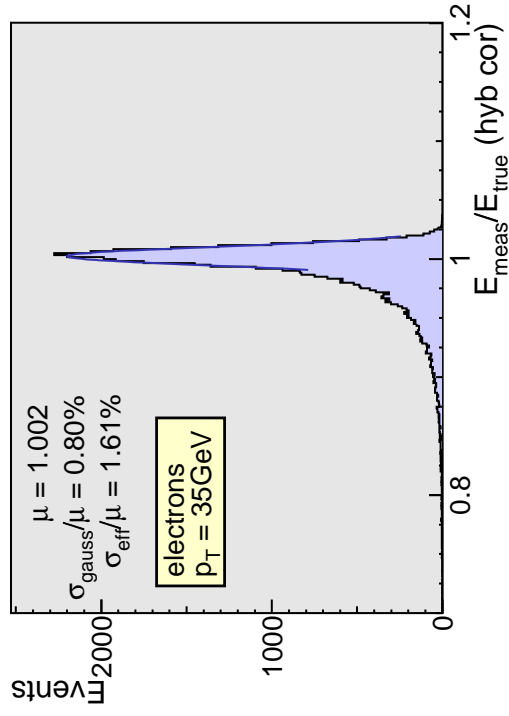

- **27.7 GeV** for the single
- **16.6 GeV** for the double

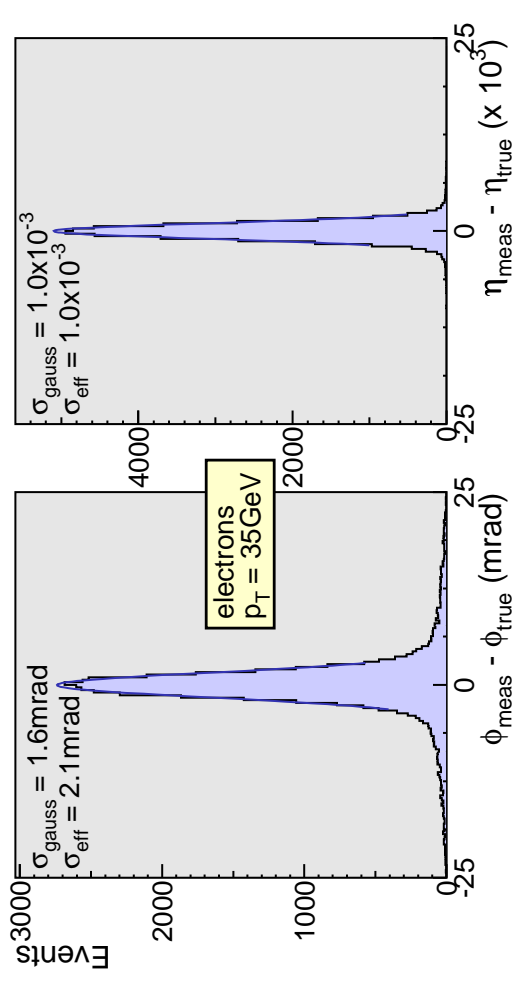

## Higher level trigger algorithms, Level 2

- HLT algorithms run on farms of commercial processors (if fast enough, the algorithms can be the same as for the final analysis)
  - Level 2: better electron energy measurement
    - Recovery of the Bremsstrahlung photons (or converted photons, at this point it is not possible to distinguish  $e/\gamma$ )
- \* Reminder: solenoidal B-field  $\rightarrow$  clusters widen in the  $\phi$ -direction

### Energy resolution

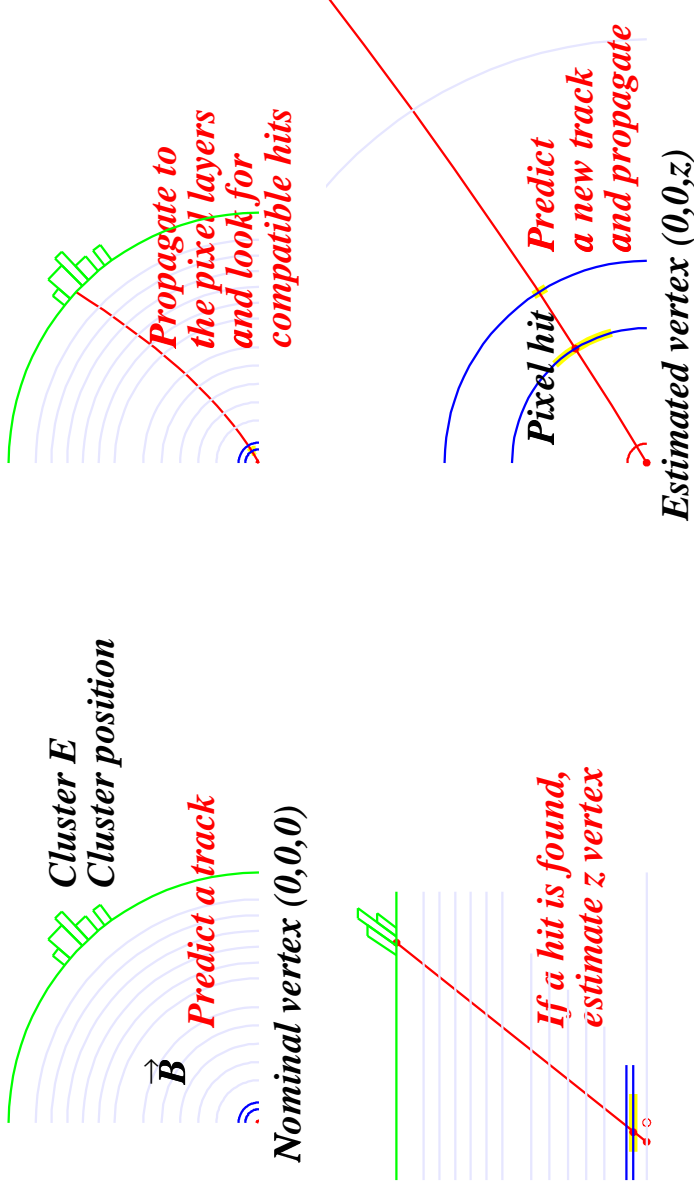

### Position resolution

## Higher level trigger algorithms, Level >2

- Level “2.5”: matching the electron clusters to the innermost pixel hits

divides the data to the electron and photon streams

- electrons: full track reconstruction,
- photons: re-apply higher  $p_T$  threshold

## Pixel match efficiency

- The efficiency vs jet rejection varying the pixel match search area for the innermost hit

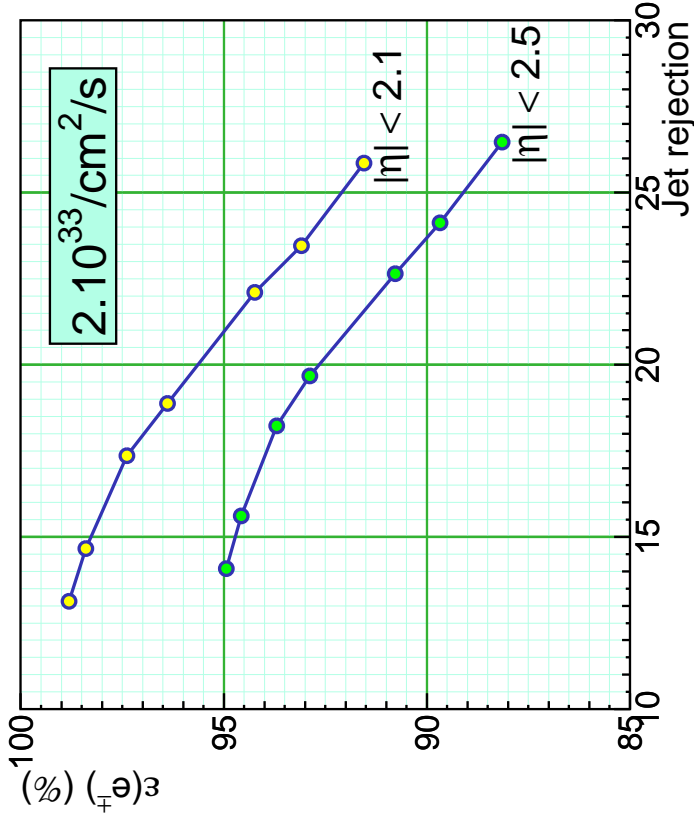

– Choose

$\Delta\phi = 0.04$ ,  $\Delta z = \pm 30$  cm

for the innermost hit,

$\Delta\phi = \pm 0.001$ ,  $\Delta z = \pm 0.05$  cm

for the second hit.

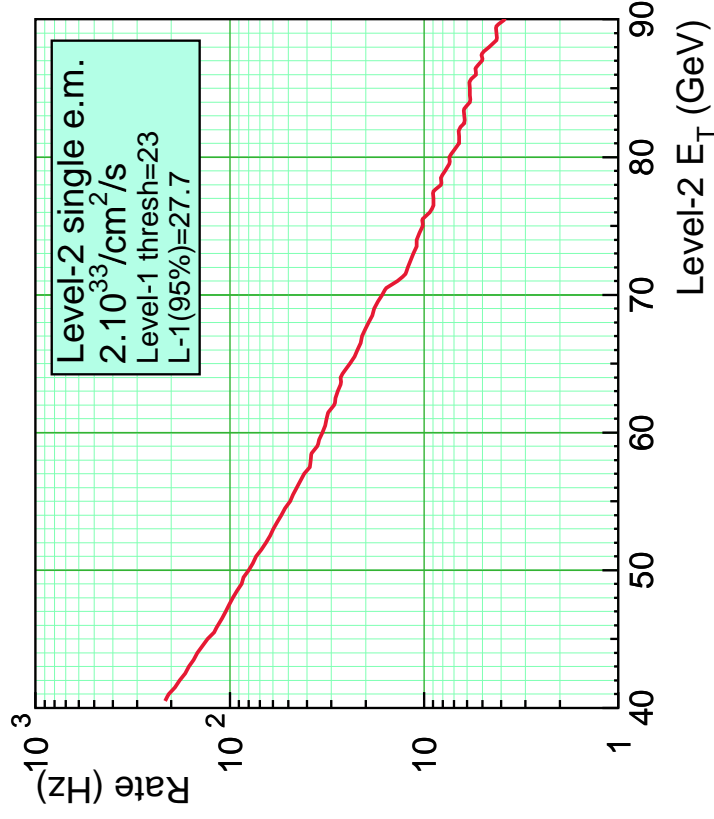

- Inevitable loss of efficiency  $|\eta| > 2.1$  due to the actual pixel geometry:

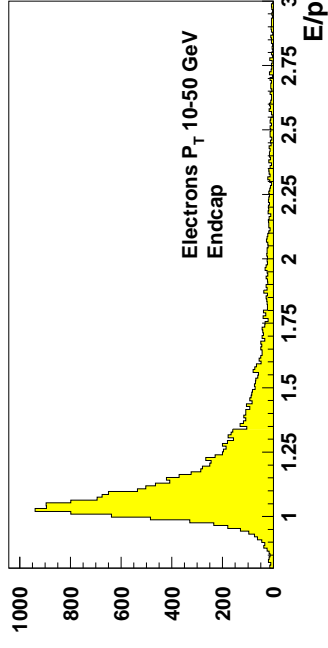

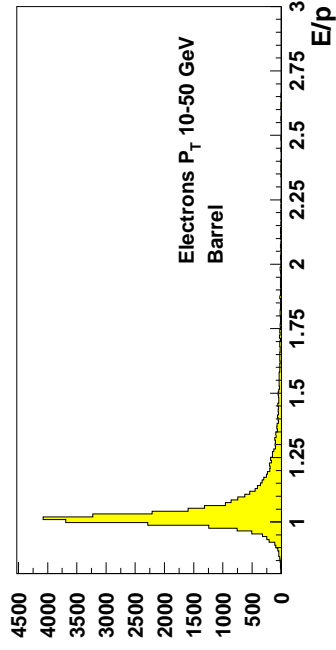

## The photon stream

- Double photon stream ( $H \rightarrow \gamma\gamma$ )
  - apply the  $H \rightarrow \gamma\gamma$  offline selection cuts of 40, 25 GeV.
- Single photon stream
  - To reduce the rate, set the threshold at  $E_T > 80$  GeV, further reduction obtained by isolation.

## Higher level trigger algorithms, Level 3 for electrons

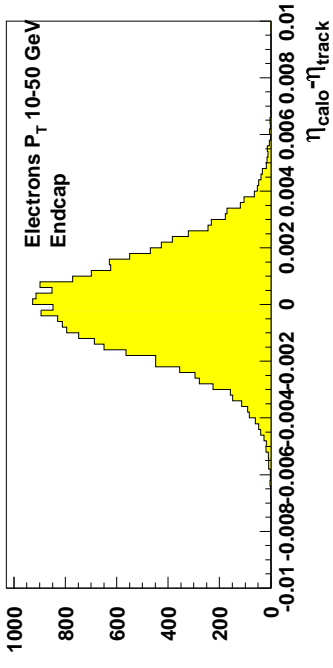

- Apply  $E/p$  ( $E$  from the calorimeter,  $p$  from the reconstructed track) for the remaining electron candidates

– require  $E/p < 1.2$  in the barrel,  $< 1.7$  in the endcaps.

## Higher level trigger algorithms, Level 3 for electrons

- Match the position in  $\eta$  obtained in the calorimeter and in the tracker  
(the most precise measurement is in  $\eta$  in the calorimeter)

- require  $\Delta\eta < 0.004$  in the barrel.
- Require small energy deposit in the hadronic calorimeter (endcaps).

## Electron selection

|   | Efficiency   | Rejection           |
|---|--|---------------------|
| <ul style="list-style-type: none"><li>● <b>Level 1</b><ul style="list-style-type: none"><li>– Single: <math>E_T &gt; 27.7</math> GeV</li><li>– Double: <math>E_T &gt; 16.6</math> GeV</li></ul></li></ul> | <b>95%</b> (loss due to the isolation requirement and gaps)<br>× <b>95%</b> (at the threshold) | <b>Rate: 3.9kHz</b> |
| <ul style="list-style-type: none"><li>● <b>Level 2</b><ul style="list-style-type: none"><li>– Reapply the thresholds</li></ul></li></ul>  | <b>95%</b> (at the threshold)  | <b>2</b>            |
| <ul style="list-style-type: none"><li>● <b>Level 2.5</b><ul style="list-style-type: none"><li>– Pixel match</li></ul></li></ul>   | <b>97%</b> $ \eta  < 2.1$<br><b>94%</b> $ \eta  < 2.5$   | <b>15</b>           |
| <ul style="list-style-type: none"><li>● <b>Level 3 Barrel</b><ul style="list-style-type: none"><li>– <math>E/p &lt; 1.2</math>, <math>\Delta\eta &lt; 0.004</math></li></ul></li></ul>                    | <b>85%</b>   | <b>6</b>            |
| <ul style="list-style-type: none"><li>● <b>Level 3 Endcap</b><ul style="list-style-type: none"><li>– <math>E/p &lt; 1.7</math>, <math>H/E &lt; 0.003</math></li></ul></li></ul>                           | <b>82%</b>   | <b>6</b>            |

## Online selection for low luminosity

- Start from 3.9 kHz Level 1 event rate:

|                 | Signal                               | Background  | Total        |
|-----------------|--------------------------------------|---|--------------|
| Single e        | $W \rightarrow e\nu$ : <b>9.7 Hz</b> | $\pi^\pm \pi^0$ overlap: <b>4Hz</b><br>$\pi^0$ conversions: <b>5Hz</b><br>$b/c \rightarrow e$ : <b>8.5 Hz</b> | <b>27 Hz</b> |
| Double e        | $Z \rightarrow ee$ : <b>1 Hz</b>     | $\approx 0$   | <b>1 Hz</b>  |
| Single $\gamma$ | $\approx 0$                          | <b>3 Hz</b>   | <b>3 Hz</b>  |
| Double $\gamma$ | $\approx 0$                          | <b>5 Hz</b>   | <b>5 Hz</b>  |
|                 |                                      |   | <b>36 Hz</b> |

- Tools not used for this selection:
  - track isolation
  - $\pi^0$  rejection with the e.m. cluster shape
  - analysis of conversion  $e^+e^-$  tracks for  $\pi^0$ 's and signal photons.

## Summary

- The full online selection chain for the initial low luminosity has been demonstrated
  - the electron trigger rate can be reduced to a required level with existing tools
  - the electron efficiency is lower than we would like to (all HLT  $\approx 70\%$ ).
- We are developing the tools to complete the online selection for high luminosity (event rate  $5 \times$  low lumi).
- Major milestones:
  - DAQ Technical Design Report in the end of the year
  - Physics Technical Design Report in 2004.
